## **Chapter 1**

## Introduction

## 1.1 Problem Statement

Churn (loss of customers to competition) is a problem for companies because it is more expensive to acquire a new customer than to keep your existing one from leaving. We are provided with a data set in which customer telephone service and call details. This problem statement is targeted at enabling churn reduction using analytics concepts.

### **1.2** Data

The objective of this Case is to predict customer behaviour. We are provided with a public dataset that has customer usage pattern and if the customer has moved or not. We have to develop an algorithm to predict the churn score based on usage pattern.

Table 1.1: Churn Reduction Train data (Columns: 1-6)

State	Account length	Area code	Phone number	International plan	Voice mail plan
KS	128	415	382-4657	No	Yes
ОН	107	415	371-7191	No	Yes
NJ	137	415	358-1921	No	No
ОН	84	408	375-9999	Yes	No
OK	75	415	330-6626	Yes	No
AL	118	510	391-8027	Yes	No

Table 1.2: Churn Reduction Train data (Columns: 7-12)

number vmail messages	total day minutes	total day calls	total day charge	total eve minutes	total eve calls
25	265.1	110	45.07	197.4	99
26	161.6	123	27.47	195.5	103
0	243.4	114	41.38	121.2	110
0	299.4	71	50.9	61.9	88
0	166.7	113	28.34	148.3	122
0	223.4	98	37.98	220.6	101

Table 1.3: Churn Reduction Train data (Columns: 13-18)

total eve charge	total night minutes	total night calls	total night charge	total intl minutes	total intl calls
16.78	244.7	91	11.01	10	3
16.62	254.4	103	11.45	13.7	3
10.3	162.6	104	7.32	12.2	5
5.26	196.9	89	8.86	6.6	7
12.61	186.9	121	8.41	10.1	3
18.75	203.9	118	9.18	6.3	6

Table 1.3: Churn Reduction Train data (Columns: 19-21)

total intl charge	Number customer service calls	Churn
2.7	1	False.
3.7	1	False.
3.29	0	False.
1.78	2	False.
2.73	3	False.
 1.7	0	False.

There are 17 predictor variable and are as follows.

- account length
- international plan
- voicemail plan
- number of voicemail messages
- total day minutes
- total day calls
- total day charge
- total evening minutes
- total evening calls
- total evening charge
- total night minutes
- total night calls
- total night charge
- total international minutes used
- total international calls made
- total international charge
- number of customer service calls made

Our target variable is churn of which we have to say whether the customer will move or not.

## Chapter 2

# Methodology

## 2.1 Pre Processing

Any predictive modeling requires that we look at the data before we start modeling. However, in data mining terms *looking at data* refers to so much more than just looking. Looking at data refers to exploring the data, cleaning the data as well as visualizing the data through graphs and plots. This is often called as **Exploratory Data Analysis**. For our data we apply pre processing techniques that we necessary. Our pre processing involves following steps:

- 1. Missing value analysis
- 2. Feature selection2.1 Correlation Analysis2.2 Chi square test of Independence
- 3. Normalization

### 2.1.1 Missing value analysis

Missing values occur when no data value is stored for the variable in an observation. Missing values are a common occurrence, and you need to have a strategy for treating them. A missing value can signify a number of different things in your data. Perhaps the data was not available or not applicable or the event did not happen. It could be that the person who entered the data did not know the right value, or missed filling in. Typically, ignore the missing values, or exclude any records containing missing values, or replace missing values with the mean, or infer missing values from existing values. We check for missing values in our data. Fortunately there are no missing values in the data that is presented.

#### 2.1.2 Feature Selection

Variable selection is an important aspect of model building. It helps in building predictive models free from correlated variables, biases and unwanted noise. It helps in selecting a subset of relevant features (variables, predictors) for use in model construction and subset of a learning algorithm's input variables upon which it should focus attention, while ignoring the rest. Let's first see how our target variable is behaving with categorical variables in dataset.

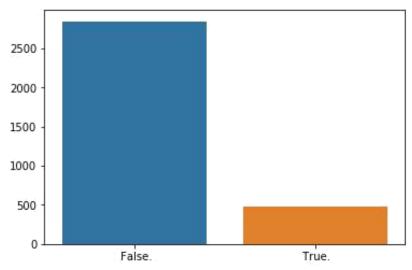

Fig 1 Churn data distribution

## Distribution of Churn with each categorical variable in data

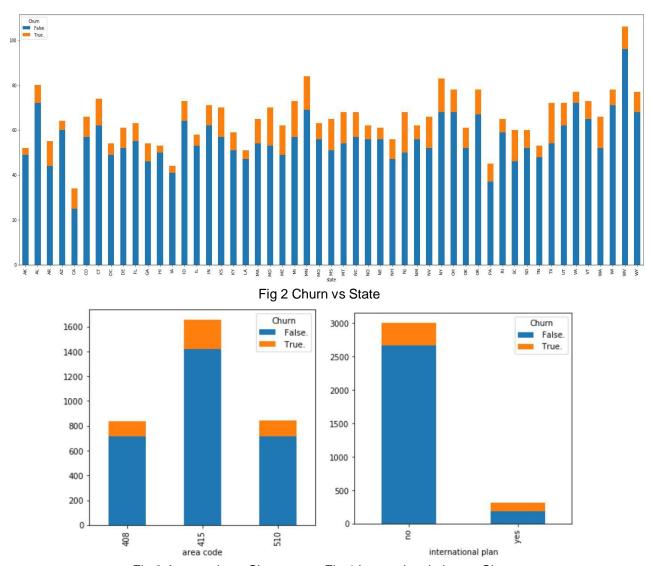

Fig 3 Area code vs Churn

Fig 4 International plan vs Churn

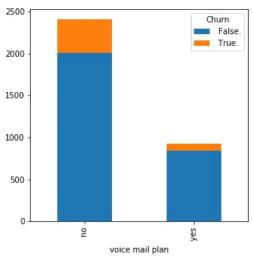

Fig 5 voice mail plan vs Churn

We will be assigning levels to our categorical data so that I will easy apply model and do pre processing techniques. Code for converting can be seen in appendix.

## **Correlation analysis**

A correlation matrix is a table showing correlation coefficients between sets of variables. Each random variable (Xi) in the table is correlated with each of the other values in the table (Xj). This allows you to see which pairs have the highest correlation. Checking at the correlation of each numerical variable has given below result.

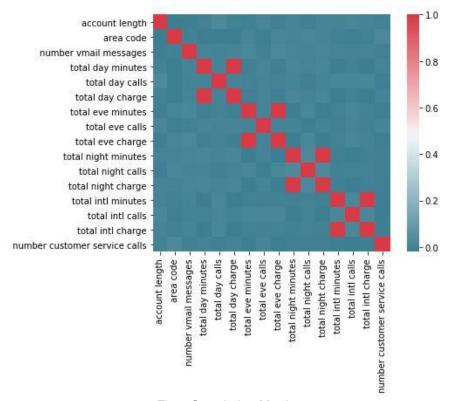

Fig 6 Correlation Matrix

Our correlation matrix shows some interesting results as follows

- 1. Total day minutes and total day charge are very highly correlated.
- 2. Total eve minutes and total eve charge are very highly correlated.
- 3. Total night minutes and total night charge are very highly correlated.
- 4. Total intl minutes and total intl charge are very highly correlated.

We can now remove one of the highly correlated variable so that our model can perform well with much accuracy.

### Chi square test of Independence

The Chi-Square test of independence is used to determine if there is a significant relationship between two categorical variables. The frequency of each category for one variable is compared across the categories of the second variable. It is used to determine whether there is a significant association between the two variables. Uses contingency table for better representation. We conduct chi square test of independence for each of the categorical variable with our target variable that is churn so that we will remove the variable that is independent with target variable. Scores of chi square test of independence of each categorical variable is as follows

#### "state"

Pearson's Chi-squared test

data: table(factor\_data\$Churn, factor\_data[, i]) X-squared = 83.044, df = 50, p-value = 0.002296

#### "phone number"

Pearson's Chi-squared test

data: table(factor\_data\$Churn, factor\_data[, i]) X-squared = 3333, df = 3332, p-value = 0.4919

#### "international plan"

Pearson's Chi-squared test with Yates' continuity correction

data: table(factor\_data\$Churn, factor\_data[, i]) X-squared = 222.57, df = 1, p-value < 2.2e-16

#### "voice mail plan"

Pearson's Chi-squared test with Yates' continuity correction

data: table(factor\_data\$Churn, factor\_data[, i]) X-squared = 34.132, df = 1, p-value = 5.151e-09

If the p value of the categorical variable is less than 0.05 then we will consider that variable that is the target variable is dependent on the categorical variable.

Therefore from both the correlation analysis and chi square test of independence we got some variable which we shouldn't consider for further processing. The variables that could be deleted are as follows

Numerical: total day minutes, total eve minutes, total night minutes, total intl minutes Categorical: phone number.

## 2.1.3 Feature Scaling

Feature scaling is a method used to standardize the range of independent variables or features of data. In data processing, it is also known as data normalization and is generally performed during the data preprocessing steps. If training an algorithm using different features and some of them are off the scale in their magnitude, then the results might be dominated by them. Therefore, the range of all features should be normalized so that each feature contributes approximately proportionately to the final distance. We use normalization here for feature scaling.

Normalization also called Min-Max scaling. It is the process of reducing unwanted variation either within or between variables. Normalization brings all of the variables into proportion with one another. It transforms data into a range between 0 and 1. We have to see the variables that are scattered highly and apply normalization. We normalize the following variables in our data so that we can process to the modeling phase. Normality check for variables is in appendix

#### **Variables**

account length, area code, number vmail messages, total day calls, total day charge, total eve calls, total eve charge, total night calls, total night charge, total intl calls, total intl charge, number customer service calls.

Formulae used for normalization is

$$Value_{new} = \frac{Value - minValue}{maxValue - minValue}$$

Now our data is ready for applying models. We will use several machine learning classifications models that reads the customer data and predicts who will churn who will not churn with highest accuracy.

## 2.2 Modeling

#### 2.2.1 Model Selection

After a thorough pre processing we will be using some classifications models on our processed data to predict the target variable.

**Decision Tree:** Decision tree is a rule. Each branch connects nodes with "and" and multiple branches are connected by "or". It can be used for classification and regression. It is a Supervised machine learning algorithm. Accept continuous and categorical variables as independent variables. Extremely easy to understand by the business users. There are many types of decision trees. We are using C5.0 model which is entropy based. When we applied this model on our train data, we got certain rules which is provided in a text file. You can also visualize the decision tree with the dot file provided in python code. The accuracy of the model can be seen as following.

C50\_Predictions 1 2 1 1331 112 2 73 151

Accuracy : 0.889

95% CI : (0.873, 0.9037)

No Information Rate: 0.8422 P-Value [Acc > NIR]: 2.662e-08

карра: 0.5556

Sensitivity: 0.9480
Specificity: 0.5741
Pos Pred Value: 0.9224
Neg Pred Value: 0.6741
Prevalence: 0.8422
Detection Rate: 0.7984
Detection Prevalence: 0.8656
Balanced Accuracy: 0.7611

'Positive' Class: 1

Random Forest: Random Forest or decision tree forests is an ensemble learning method for classification, regression and other tasks. It consists of an arbitrary number of simple trees, which are used to determine the final outcome. For classification problems, the ensemble of simple trees vote for the most popular class. Using tree ensembles can lead to significant improvement in prediction accuracy (i.e., better ability to predict new data cases). The goal of using a large number of trees is to train enough that each feature has a chance to appear in several models. We can see certain rules of random forest in the R code. The accuracy of the model is as follows.

```
RF_Predictions
       1
            2
  1 1434
            9
    158
           66
               Accuracy : 0.9058
                 95% CI: (0.8844, 0.9138)
    No Information Rate: 0.955
    P-Value [Acc > NIR] : 1
                  Kappa : 0.4011
 Mcnemar's Test P-Value : <2e-16
           Sensitivity: 0.9008
           Specificity: 0.8800
        Pos Pred Value: 0.9938
        Neg Pred Value: 0.2946
            Prevalence: 0.9550
        Detection Rate: 0.8602
  Detection Prevalence: 0.8656
     Balanced Accuracy: 0.8904
      'Positive' Class: 1
```

**Logistic Regression:** Logistic regression is the appropriate regression analysis to conduct when the dependent variable is binary. Cases where the dependent variable has more than two outcome categories may be analyzed in multinomial logistic regression, or, if the multiple categories are ordered, in ordinal logistic regression. Logistic regression is used to describe data and to explain the relationship between one dependent binary variable and one or more nominal, ordinal, interval or ratio-level independent variables. The summary of logistic model can be seen as following:

```
Call:
glm(formula = Churn ~ ., family = "binomial", data = train)
Deviance Residuals:
    Min 1Q Median 3Q Max -1.9135 -0.4977 -
0.3120 -0.1659 3.0484
```

This model works with an accuracy of 86.38%

**K-NN Implementation:** K-Nearest Neighbors algorithm (KNN) is a non-parametric method used for classification and regression. KNN is a type of instance-based learning or lazy learning and simplest of all machine learning algorithms. Even with such simplicity, it can give highly competitive results. It is more widely used in classification problems in the industry. KNN fairs across all parameters of considerations. It is commonly used for its easy of interpretation and low calculation time. K-NN is a lazy learner because it doesn't learn a discriminative function from the training data but "memorizes" the training dataset instead. The accuracy of KNN model is

```
KNN_Predictions
      1
  1 1430
          210
  2
     13
           14
              Accuracy : 0.8662
                95% CI: (0.8489, 0.8822)
   No Information Rate: 0.8656
   P-Value [Acc > NIR] : 0.4892
                  Kappa : 0.0851
Mcnemar's Test P-Value : <2e-16
           Sensitivity: 0.9910
           Specificity: 0.0625
        Pos Pred Value: 0.8720
        Neg Pred Value: 0.5185
            Prevalence: 0.8656
        Detection Rate: 0.8578
  Detection Prevalence: 0.9838
     Balanced Accuracy: 0.5267
      'Positive' Class: 1
```

**Naïve Bayes:** It is a classification technique based on Bayes' Theorem with an assumption of independence among predictors. In simple terms, a Naive Bayes classifier assumes that the presence of a particular feature in a class is unrelated to the presence of any other feature. Naive Bayes model is easy to build and particularly useful for very large data sets. Along with simplicity, Naive Bayes is known to outperform even highly sophisticated classification methods. The accuracy of Naïve Bayes model is

```
predicted
observed
            1
      1 1349
               94
      2
          120 104
               Accuracy : 0.8716
                 95% CI: (0.8546, 0.8873)
    No Information Rate: 0.8812
    P-Value [Acc > NIR] : 0.89327
                  Kappa : 0.4197
 Mcnemar's Test P-Value: 0.08746
            Sensitivity: 0.9183
            Specificity: 0.5253
         Pos Pred Value: 0.9349
         Neg Pred Value: 0.4643
             Prevalence: 0.8812
         Detection Rate: 0.8092
   Detection Prevalence: 0.8656
      Balanced Accuracy: 0.7218
       'Positive' Class : 1
```

Therefore from all the above models we can see that random forest classifier gives us the highest accuracy in predicting the target variable. Now we must see several error metrics and fix our model on the test dat a.

## **Chapter 3**

## Conclusion

#### 3.1 **Model Evaluation**

Model evaluation is done on basis of evaluation metrics or error metrics. Evaluation metrics explain the performance of a model. An important aspect of evaluation metrics is their capability to discriminate among model results. Simply, building a predictive model is not our motive. But, creating and selecting a model which gives high accuracy on out of sample data. Hence, it is crucial to check accuracy or other metric of the model prior to computing predicted values. In our data as we applied classification models we have error metrics like confusion matrix out of which we can check specificity, recall, false negative rate, false positive rate. We will evaluate error metrics for each of the model that is applied

Confusion matrix has True Positive(TP), True Negative(TN), False Positive(FP), False Negative(FN)

True Positive is the number of correct predictions that an instance is Yes, False Negative is the number of incorrect predictions that an instance is No, False Positive is the number of incorrect of predictions that an instance Yes, and True Negative is the number of correct predictions that an instance is No.

#### **Decision Tree:**

Confusion Matrix

C50 Predictions

1 1 1331 112 73 151

Accuracy: (TP+TN)/Total observations = 0.889 Sensitivity or Recall: TP/TP+FN = 0.9480

Specificity: TN/TN+FP = 0.5741

False positive rate: FP/FP+TN = 0.6741 False Negative rate: FN/FN+TP = 0.3259

#### **Random Forest:**

Confusion Matrix

RF\_Predictions

2 1 1 1434 9 148

Accuracy: (TP+TN)/Total observations = 0.9058

Sensitivity or Recall: TP/TP+FN = 0.9064

Specificity: TN/TN+FP = 0.8941

False positive rate: FP/FP+TN = 0.3393 False Negative rate: FN/FN+TP = 0.6607

### **Logistic Regression:**

Confusion Matrix

logit\_Predictions

Accuracy: (TP+TN)/Total observations = 0.8638

Sensitivity or Recall: TP/TP+FN = 0.9064

Specificity: TN/TN+FP = 0.8941

False positive rate: FP/FP+TN = 0.2947 False Negative rate: FN/FN+TP = 0.7053

#### **KNN** Implementation:

Confusion Matrix

Accuracy: (TP+TN)/Total observations = 0.8662

Sensitivity or Recall: TP/TP+FN = 0.9910

Specificity: TN/TN+FP = 0.0625

False positive rate: FP/FP+TN = 0.5185 False Negative rate: FN/FN+TP = 0.4814

### Naïve Bayes:

Confusion Matrix

KNN\_Predictions

Accuracy: (TP+TN)/Total observations = 0.8716

Sensitivity or Recall: TP/TP+FN = 0.9183

Specificity: TN/TN+FP = 0.5253

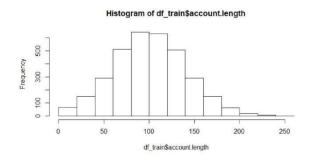

False positive rate: FP/FP+TN = 0.4643 False Negative rate: FN/FN+TP = 0.5357

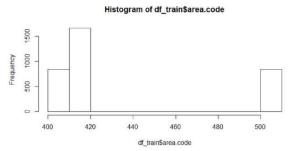

### 3.2 Model Selection

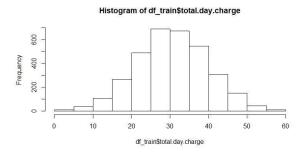

We can see that all models perform comparatively on average and therefore we select either decision tree or random forest classifier models for better prediction.
